*Abstract*  
(Not Verified)

Literature survey has revealed that the recently developed grade of stainless steel 409M has not been much researched upon. This has inspired the present research work. The strength of a welded joint depends upon bead geometry parameters like depth of penetration, weld width, height of reinforcement, weld dilution, weld penetration shape factor and weld reinforcement form factor. These parameters in turn depend upon input parameters like weld current, voltage, welding speed, nozzle to plate distance etc. A mathematical model was developed to relate the response parameters with the input parameters and the results were validated. The knowledge of temperature distribution during and after welding is essential as it decides the formation of different microstructures which further affect the performance of the weld joint. A temperature sensing and recording system was used to record the temperature at various distances from the weld line and real time graphs were plotted. From these graphs, weld isotherms were plotted which were helpful in predicting the important weld bead dimensions. Angular distortion is almost inevitable in welding processes due to non uniform rates of cooling. This distortion has negative effects on the geometry of the weld and should be minimum. A mathematical model was developed to study the effects of input parameters like welding current, welding speed, voltage and groove angle etc on angular distortion. During welding due to non uniform heating and cooling cycles, residual stresses are induced in the welds which have a detrimental effect on the strength and the service life of the weld. Residual stresses were measured and their distribution was investigated in the present research work. Finally, metallurgical investigations were carried out to ascertain the type of microstructures formed in different zones of weld. To corroborate the results of optical microscopy, microstructural study was followed by a detailed microhardness survey.

*Contents*

1. Introduction 2. Literature Survey 3. Development of a Mechanized Welding Unit 4. Calibration of Welding Unit 5. Weld Bead Geometry and Shape Relationships 6. Development of Mathematical Models for Prediction of Weld Bead Dimensions 7. Measurement and Analysis of Residual Stresses 8. Metallurgical Transformations 9. Heat Flow in Welding 10. Development of Mathematical Model for Angular Distortion in Butt Welds 11. Concluding Remark. References. Appendix.
